# 1 Overview

Kotlin is a Cross-platform, compiled, statically typed, general-purpose programming language with type inference.

- Kotlin is an official language for Android.

```
1 // Hello world program in Kotlin
2 package com.rashik
3
4 fun main (args: Array<String>) {
5     println("Hello World!");
6 }
```

- The Kotlin files are saved with an extension **.kt**
- **Main function** is the **entry point** of a Kotlin program or application.
- Kotlin can be compiled for several different platforms

## 1.1 Comments

- In Kotlin, single line comments are defined using `//` and multiline comments using `/* */`.

```
1 /*
2     It is a
3     multiline
4     comment
5 */
6 fun sum(a: Int, b: Int): Int {
7     // It is a single line comment
8     return a + b
9 }
```

## 2 Variables

Variables are used to store information to be referenced and manipulated in a computer program. They also provide a way of labeling data with a descriptive name, so our programs can be understood more clearly by the reader and ourselves. It is helpful to think of variables as containers that hold information. Their sole purpose is to label and store data in memory.

### 2.1 Read-only variables

- These variables are declared using keyword `val`.
- These variable can be assigned a value only once.
- If we re-assign these variables it'll throw the compile-time error.

#### 2.1.1 Constants

- If the value is truly constant and its type is a string or primitive type then we can declare a constant variable using keyword `const`.
- We can only declare a constant at the top level of a file or inside an object declaration (but not inside a class declaration).

### 2.2 Mutables

- These variables are declared using keyword `var`.
- These variable can be re-assign hence they are mutable.

Variable name should be in `lowerCamelCase`.

A variable only exists inside the scope (curly-brace-enclosed block of code; more on that later) in which it has been declared - so a variable that's declared inside a loop only exists in that loop; you can't check its final value after the loop.

```
1 // Read-only variable
2 val myName = "Rashik Ansar"
3
4 // Mutable
5 var year = 2020
6
7 // Constant
8 const val pi = 3.14
9
10 println("Hello $myName. This is $year A.D")
11 println("Pi value is $pi")
```

Kotlin has a feature called String Interpolation. This feature allows us to directly insert a template expression inside a String. Template expressions are tiny pieces of code that are evaluated and their results are concatenated with the original String. A template expression is prefixed with `$` symbol.

### 3 Data types

- In Kotlin we need not to specify types of a variable explicitly unless we're not initializing the variable. (Check code of variables we didn't specify any types.)
- It has type inference feature which automatically assigns type to the variable based on the context or value provided.

1 Byte = 8 bits.

value range of  $n$  bits is  $2^n$

**Table 3.1:** Storage size of different Data types

Data type	Storage size
Byte	1 Byte (8 bits)
Short	2 Bytes (16 bits)
Int	4 Bytes (32 bits)
Long	8 Bytes (64 bits)
Float	4 Bytes (32 bits)
Double	8 Bytes (64 bits)
Boolean	1 Byte (8 bits)
Char (UTF-16)	2 Bytes (16 bits)

```
1 fun main (args: Array<String>) {  
2     // Integer Types  
3     val myByte: Byte = 12  
4     val myShort: Short = 10804  
5     val myInt: Int = 123456789  
6     val myLong: Long = 12_345_678_900  
7 }
```

```
8 // Floating Types
9 val myFloat: Float = 15.67F
10 val myDouble: Double = 3.14
11
12 // Boolean Type
13 val isSunny: Boolean = true
14 val isRainy: Boolean = false
15
16 // Characters
17 val myChar: Char = 'A'
18
19 // String
20 val myString: String = "This is my string..!"
21 // Any character in a string can be accessed using square bracket
   notaion.
22 // Index starts at 0 instead of 1
23 var firstCharInMyString = myString[0]
24 var lastCharInMyString = myString[myString.length - 1]
25 }
```

`String` is not a primitive data type. String literal (which you can only do with double quotes), is an immutable sequence of UTF-16 code units. `ByteArray` is a fixed-size (but otherwise mutable) byte array (and `String` can specifically not be used as a byte array).

Normal strings are defined within the double quotes (" ") and it can contain escape characters.

Where as Raw Strings are declared within triple double quotes ("\"") and it should not contain escape characters.

## 4 Operators

- Operators are special symbols (characters) that carry out operations on operands (variables and values).

### 4.1 Arithmetic Operators

**Table 4.1:** Arithmetic Operators

Operator	Description	Example
+	Addition	15 + 5
−	Subtraction	15 − 5
*	Multiplication	15 * 5
/	Division	15/5
%	Modulus	15%5

```
1 fun main(args: Array<String>) {
2     val number1 = 15
3     val number2 = 5
4     var result: Int
5
6     result = number1 + number2
7     println("number1 + number2 = $result")
8
9     result = number1 - number2
10    println("number1 - number2 = $result")
11
12    result = number1 * number2
13    println("number1 * number2 = $result")
14
15    result = number1 / number2
16    println("number1 / number2 = $result")
}
```

```

17
18     result = number1 % number2
19     println("number1 % number2 = $result")
20 }

```

The + operator is also used for concatenation of strings.

## 4.2 Assignment Operators

**Table 4.2:** Assignment Operators

Operator	Equivalent	Example
=	<code>var a = 20</code>	<code>var a = 20</code>
+=	<code>a = a + 5</code>	<code>a += 5</code>
-=	<code>a = a - 5</code>	<code>a -= 5</code>
*=	<code>a = a * 5</code>	<code>a *= 5</code>
/=	<code>a = a / 5</code>	<code>a /= 5</code>
%=	<code>a = a % 5</code>	<code>a %= 5</code>

```

1 fun main(args: Array<String>) {
2     var number = 20
3
4     number += 5
5     println("number = $number")
6
7     number -= 5
8     println("number = $number")
9
10    number *= 5
11    println("number = $number")
12
13    number /= 5
14    println("number = $number")
15
16    number %= 5
17    println("number = $number")
18 }

```

## 4.3 Comparison Operators

**Table 4.3:** Comparison Operators

Operator	Description	Example
<	Less than	<code>a &lt; b</code>
>	Greater than	<code>a &gt; b</code>
<=	Less than or equal to	<code>a &lt;= b</code>
>=	Greater than or equal to	<code>a &gt;= b</code>
==	is equal to	<code>a == b</code>
!=	not equal to	<code>a != b</code>

```
1 fun main(args: Array<String>) {
2
3     val a = -4
4     val b = 12
5
6     val isEqual = a == b      // it returns false
7     println("isEqual is $isEqual")
8
9     println("isNotEqual is ${a != b}")
10
11
12     val max = if (a > b) {
13         println("a is larger than b.")
14         a
15     } else {
16         println("b is larger than a.")
17         b
18     }
19
20     println("max = $max")
21 }
```

## 4.4 Unary Operators

**Table 4.4:** Unary Operators

Operator	Description	Example
++	Increment	<code>a++</code> or <code>++a</code>
--	Decrement	<code>a--</code> or <code>--a</code>
+	Unary plus	<code>+a</code>
-	Unary Minus (inverts sign)	<code>-a</code>
!	Not (inverts value)	<code>!a</code>

```

1 fun main(args: Array<String>) {
2     val a = 1
3     val b = true
4     var c = 24
5
6     var result: Int
7
8     result = -a
9     println("-a = $result")
10
11    println("!b = ${!b}")
12
13    println("--c = ${--c}")
14    println("c-- = ${c--}")
15    println("c = $c")
16    println("++c = ${++c}")
17    println("c++ = ${c++}")
18    println("c = $c")
19 }

```

## 4.5 Logical Operators

**Table 4.5:** Logical Operators

Operator	Description	Example
	or	<code>(a&gt;b)    (a&gt;c)</code>
&&	and	<code>(a&gt;b) &amp;&amp; (a&gt;c)</code>

```
1 fun main(args: Array<String>) {  
2  
3     val a = 54  
4     val b = 28  
5     val c = -12  
6     val result: Boolean  
7  
8     result = (a>b) && (a>c)    // result = (a>b) and (a>c) = true  
9     println(result)  
10 }
```

## 4.6 in Operator

- In operator is used to check whether an object belongs to a collection.

Operator	Equivalent	example
<code>in</code>	<code>b.contains(a)</code>	<code>a in b</code>
<code>!in</code>	<code>!b.contains(a)</code>	<code>a !in b</code>

There are no bitwise and bitshift operators in Kotlin.

To perform these task, various functions (supporting infix notation) are used: `shl`, `shr`, `xor` etc.

## 5 Control Flow

### 5.1 if Expression

- In Kotlin, if is an expression, i.e. it returns a value.
- It is used to control the flow of program structure.

```
1 fun main() {
2     val a = 10
3     val b = 15
4
5     // Traditional usage
6     var max = a
7     if (a < b) max = b
8
9     println("Max is $max")
10
11    // With else
12    var max1: Int
13    if (a > b) {
14        max1 = a
15    } else {
16        max1 = b
17    }
18
19    println("Max1 is $max1")
20
21    // As expression
22    val max2 = if (a > b) a else b
23
24    println("Max2 is $max2")
25 }
```

**Listing 5.1:** Compare height of two persons

```
1 fun main() {
2     var person1Height = 170
3     var person2Height = 189
4
5     if (person1Height > person2Height){
6         println("Person 1 is taller than Person 2")
7     }
```

```
7 }else if (person1Height == person2Height) {
8     println("Person 1 and Person 2 are of same height")
9 }else{
10     println("Person 2 is taller than Person 1")
11 }
12 }
```

**Listing 5.2:** Greet if his name is Rashik

```
1 fun main() {
2     val name = "Rashik"
3
4     if(name == "Rashik") {
5         println("Welcome home $name")
6     } else {
7         println("Who are you?")
8     }
9 }
```

If you're using **if** as an expression rather than a statement (for example, returning its value or assigning it to a variable), the expression is required to have an else branch.

## 5.2 When Expression

- **when** replaces the switch operator of C-like languages.
- **when** matches its argument against all branches sequentially until some branch condition is satisfied.
- **when** can be used either as an expression or as a statement.

If **when** is used as an expression, the else branch is mandatory.

```
1 fun main() {
2     var season = 3
3
4     when(season) {
5         1 -> println("Spring")
6         2 -> println("Summer")
7         3 -> {
8             println("Fall")
9             println("Autumn")
10        }
11        4 -> println("Winter")
12    }
```

```
12     else -> println("Invalid season")
13 }
14 }
```

```
1 fun main() {
2     var month = 3
3     when (month) {
4         in 3..5 -> println("Spring")
5         in 6..8 -> println("Summer")
6         in 9..11 -> println("Fall")
7         12, 1, 2 -> println("Winter")
8         else -> println("Invalid month")
9     }
10 }
```

```
1 fun main() {
2     var x: Any = 18.97
3
4     when (x) {
5         is Int -> println("$x is Int")
6         is Double -> println("$x is Double")
7         is String -> println("$x is String")
8         else -> println("$x is not Int, Double, or String.")
9     }
10 }
```

## 5.3 Loops

Loops are used to iterate a part of program several time.

- There are three loops in kotlin. They are
  1. While Loop
  2. Do - While Loop
  3. For Loop

### 5.3.1 While Loop

- While loop executes a block of code repeatedly as long as the given condition is true.

```
1 fun main() {
2     var x = 10
3     while(x > 0) {
4         print("$x\t")
5         x--
6     }
7 }
```

```
6 }  
7 }
```

```
1 fun main() {  
2     var x = 1  
3     while(x <= 10) {  
4         println("4 * $x\t= ${4*x}")  
5         x++  
6     }  
7 }
```

```
1 // Change room temp from cold to comfortable.  
2 fun main() {  
3     var feltTemp = "cold"  
4     var roomTemp = 10  
5  
6     while (feltTemp == "cold") {  
7         roomTemp++  
8         if (roomTemp >= 20) {  
9             feltTemp = "comfortable"  
10            println("It's comfy now.")  
11        }  
12    }  
13 }
```

### 5.3.2 Do-While Loop

- It is similar to **while** loop but the only difference is even though the condition is false, loop will execute atleast once.

```
1 // Even though the condition is false it executed once.  
2 fun main() {  
3     var x = 15  
4     do {  
5         println("$x")  
6         x++  
7     } while (x <= 10)  
8 }
```

- When do we need do-while loop?
  - ex: Menu programs.

### 5.3.3 For Loop

- **for** loop iterates through anything that provides an iterator.

```
1 fun main() {
2     for(num in 1..10){
3         print("$num\t")
4     }
5
6     println()
7
8     for(i in 1 until 10){
9         print("$i\t")
10    }
11
12    println()
13
14    for(i in 10 downTo 1 step 2){
15        print("$i\t")
16    }
17 }
```

## 5.4 Returns and Jumps

- Kotlin has three structural jump expressions
  - **return**: By default returns from the nearest enclosing function or anonymous function.
  - **break**: Terminates the nearest enclosing loop
  - **continue**: Proceeds to the next step of the nearest enclosing loop

### 5.4.1 Break and Continue Labels

Any expression in Kotlin may be marked with a label. Labels have the form of an identifier followed by the @ sign, for example: abc@, fooBar@ are valid labels (see the grammar). To label an expression, we just put a label in front of it

```
1 fun main(args: Array<String>) {
2     loop@ for (i in 1..3) {
3         for (j in 1..3) {
4             println("i = $i and j = $j")
5             if (i == 2)
6                 break@loop
7         }
8     }
9 }
```

```
1 fun main(args: Array<String>) {
2     labelname@ for (i in 1..3) {
```

```
3     for (j in 1..3) {  
4         println("i = $i and j = $j")  
5         if (i == 2) {  
6             continue@labelname  
7         }  
8         println("this is below if")  
9     }  
10 }  
11 }
```

## 6 Functions

Function is a group of inter related block of code which performs a specific task. Function is used to break a program into different sub module. It makes reusability of code and makes program more manageable.

- **Standard library function:** Kotlin Standard library function is built-in library functions which are implicitly present in library and available for use.
- **User defined function :** It is a function which is created by user. User defined function takes the parameter(s), perform an action and return the result of that action as a value
- Kotlin Functions are declared using `fun` keyword.

```
1 fun functionName() {  
2     // body of the function  
3 }
```

- We have to call the function to run the code inside the function by using function name followed by `()`.

```
1 functionName()
```

Check out this link for [Parameter vs Argument](#)

```
1 fun main() {  
2     var result = sum(5,9)  
3     myFunction()  
4     println("Sum of 9 and 5 is $result")  
5     println("Average of 5.3 and 13.37 is ${avg(5.3, 13.37)}")  
6 }  
7  
8 fun myFunction() {  
9     println("From myFunction")  
10 }  
11  
12 fun sum(a:Int, b:Int ):Int {  
13     return a+b  
14 }
```

```
14 }
15
16 fun avg(a: Double, b: Double): Double {
17     return (a+b)/2
18 }
```

```
1 // Example of recursive function
2 fun main(args: Array<String>) {
3     val number = 5
4     val result = factorial(number)
5     println("Factorial of $number = $result")
6 }
7
8 fun factorial(n: Int): Long {
9     return if(n == 1){
10         n.toLong()
11     } else {
12         n*factorial(n-1)
13     }
14 }
```

```
1 fun main(args: Array<String>) {
2     run()
3     run(9, 'a')
4     run(8)
5     run(letter='h')
6 }
7 fun run(num:Int= 5, letter: Char ='x'){
8     println("parameter in function definition $num and $letter")
9 }
```

## 7 Kotlin Null Safety

Kotlin null safety is a procedure to eliminate the risk of null reference from the code. Kotlin compiler throws `NullPointerException` immediately if it found any `null` argument is passed without executing any other statements.

Kotlin's type system is aimed to eliminate `NullPointerException` from the code. `NullPointerException` can only possible on following causes:

1. An forcefully call to throw `NullPointerException()`
2. An uninitialized of this operator which is available in a constructor passed and used somewhere.
3. Use of external Java code as Kotlin is Java interoperability.

### 7.1 Kotlin Nullables

Kotlin types system differentiates between references which can hold null (nullable reference) and which cannot hold null (non null reference). Normally, types of String are not nullable. To make string which holds null value, we have to explicitly define them by putting a ? behind the String as: `String?`

```
1 fun main() {
2     var name: String = "Rashik"
3     // var nullableName: String? = null
4     var nullableName: String? = "Rashik"
5
6     var nameLen = name.length
7     // if nullable name is null then assign value null else assign
8     // length of nullabl name
9     var nullableNameLen = nullableName?.length
10
11     println("$name has $nameLen characters")
12     println("$nullableName has $nullableNameLen characters")
13 }
```

### 7.1.1 Elvis Operator

When we have a nullable reference `nullableName`, we can say “if `nullableName` is not null, use it, otherwise use some non-null value (“Guest”)”.

```
1 fun main() {
2     var nullableName: String? = null
3
4     val name: String = nullableName ?: "Guest"
5
6     println("$name")
7     println("$nullableName ")
8 }
```

### 7.1.2 The !! Operator

The third option is for `NullPointerException`-lovers: the **not-null assertion operator** (`!!`) converts any value to a non-null type and throws an exception if the value is null. We can write `nullableName !!`, and this will return a non-null value of `nullableName` or throw an `NullPointerException` if `nullableName` is `null`

```
1 fun main() {
2     var nullableName: String? = "Rashik"
3
4     val name: String = nullableName ?: "Guest"
5
6     println("$name")
7     println("$nullableName ")
8
9     // if the value of nullableName is null then the
10    // following line will throw NullPointerException
11    nullableName!!.toLowerCase()
12 }
```

## 8 Object Oriented Programming

Kotlin supports both object oriented programming (OOP) as well as functional programming. Object oriented programming is based on real time objects and classes. Kotlin also support pillars of OOP language such as **encapsulation**, **inheritance** and **polymorphism**.

### 8.1 Class

A class is a blueprint for the objects which have common properties. Kotlin classes are declared using keyword **class**. Kotlin class has a class header which specifies its type parameters, constructor etc. and the class body which is surrounded by curly braces.

Class body contains the data members(properties) and member functions(methods or behaviour).

- The followin two lines are same.

```
1 class Person constructor(firstName: String, lastName: String) {}
```

```
1 class Person(firstName: String, lastName: String) {}
```

### 8.2 Object

Object is real time entity or may be a logical entity which has state and behavior. It has the characteristics: - state: it represents value of an object. - behavior: it represent the functionality of an object.

Object is used to access the properties and member function of a class. Kotlin allows to create multiple object of a class.

Properties and member function of class are accessed by . operator using object.

```
1 fun main() {  
2     var rashik = Person("Rashik Ansar", "Shaik")  
3     println(rashik.hobby)  
4 }
```

```
1 fun main() {
2     var unknown = Person()
3
4     var rashik = Person("Rashik Ansar", "Shaik")
5     rashik.stateHobby()
6     rashik.hobby = "Play video games"
7     rashik.stateHobby()
8
9     var kevin = Person("Kevin", "Hart", 40)
10    kevin.hobby = "Cracking jokes"
11    kevin.stateHobby()
12 }
13
14
15 class Person(firstName: String = "John", lastName: String = "Doe") {
16     // Data members
17     var firstName: String? = null
18     var lastName: String? = null
19     var age: Int? = null
20     var hobby: String = "watch Netflix"
21
22     // Initializer block
23     init {
24         this.firstName = firstName
25         this.lastName = lastName
26         println("First Name: $firstName, Last Name: $lastName")
27     }
28
29     // Member secondary constructor
30     constructor(firstName: String, lastName: String, age: Int): this(
31         firstName, lastName) {
32         this.age = age
33         println("First Name: $firstName, Last Name: $lastName, age: $age")
34     }
35
36     // Member functions
37     fun stateHobby() {
38         println("$firstName's hobby is $hobby")
39     }
40 }
```

Why kotlin allows to declare variable with the same name as parameter inside the method?

```
1 fun main() {
2     var myCar = Car()
```

```
3     println("Brand is: ${myCar.myBrand}")
4     myCar.maxSpeed = 242
5     println("Max Speed is ${myCar.maxSpeed}")
6     println("Model is ${myCar.myModel}")
7 }
8
9 class Car() {
10     lateinit var owner: String
11
12     val myBrand: String = "bmw"
13     get() {
14         return field.toUpperCase()
15     }
16
17     var maxSpeed: Int = 250
18     get() = field
19     set(value) {
20         field = if(value >= 0 && value <= 250) value else throw
                IllegalArgumentException("Invalid speed")
21     }
22
23     var myModel: String = "M5"
24     private set
25
26     init {
27         this.owner = "Frank"
28     }
29
30 }
```

```
1 // data class
2 data class User(val id: Long, var name: String)
3
4 fun main() {
5     val user1 = User(1, "Rashik Ansar")
6
7     println(user1.name)
8     println(user1.id)
9
10    println(user1.component1())
11    println(user1.component2())
12
13
14    val (id, name) = user1
15    println("id: $id \t name: $name")
16
17    user1.name = "Alpha"
18    println(user1.name)
19
20    val user2 = user1.copy(name="Alpha")
21    println(user1.equals(user2))
```

```
22     println(user2.name)
23 }
```

## 8.3 Inheritance

The class that inherits the features of another class is called the **Sub class** or the **Child class** or the **Derived class**. The class whose features are inherited is known as **Super class** or **Parent class** or **Base class**.

All classes in Kotlin have a common superclass Any, that is the default superclass for a class with no supertypes declared

Any has three methods: `equals()`, `hashCode()` and `toString()`. Thus, they are defined for all Kotlin classes.

By default, Kotlin classes are **final**: they **can't be inherited**. To make a class inheritable, mark it with the `open` keyword.

```
1 fun main() {
2     var audiA3 = Car("A3", "Audi")
3     var teslaS = ElectricCar("S-Model", "Tesla", 85.0)
4
5     audiA3.drive(200.0)
6     teslaS.drive(200.0)
7     teslaS.drive()
8 }
9
10 // Super class of electric car
11 open class Car(val name: String, val brand: String) {
12     open var range: Double = 0.0
13
14     fun extendedRange(amount: Double) {
15         if (amount > 0) {
16             range += amount
17         }
18     }
19
20     open fun drive(distance: Double) {
21         println("Drove for $distance KMs")
22     }
23 }
24
25 // sub class of Car
26 class ElectricCar(name:String, brand: String, batteryLife: Double): Car
    (name, brand) {
```

```
27     override var range = batteryLife * 6
28
29     override fun drive(distance: Double) {
30         println("Drove for $distance KMs on battery")
31     }
32
33     fun drive() {
34         println("Drove for $range KMs on electricity")
35     }
36 }
```

## 8.4 Abstract class

A class and some of its members may be declared abstract. An abstract member does not have an implementation in its class. Note that we do not need to annotate an abstract class or function with `open` – it goes without saying.

We can override a non-abstract open member with an abstract one

Abstract classes are always `open`. You do not need to explicitly use `open` keyword to inherit subclasses from them.

```
1  abstract class Person(name: String) {
2      init {
3          println("My name is $name.")
4      }
5
6      fun displaySSN(ssn: Int) {
7          println("My SSN is $ssn.")
8      }
9
10     abstract fun displayJob(description: String)
11 }
12
13 class Teacher(name: String): Person(name) {
14
15     override fun displayJob(description: String) {
16         println(description)
17     }
18 }
19
20 fun main(args: Array<String>) {
21     val jack = Teacher("Jack Smith")
22     jack.displayJob("I'm a mathematics teacher.")
23     jack.displaySSN(23123)
```

```
24 }
```

Kotlin interfaces are similar to abstract classes. However, interfaces cannot store state whereas abstract classes can. Interfaces cannot have constructors.

## 8.5 Interface

Interfaces in Kotlin can contain declarations of abstract methods, as well as method implementations. - Using interface supports functionality of multiple inheritance. - It can be used achieve to loose coupling. - It is used to achieve abstraction.

```
1  interface Drivable {
2      val maxSpeed: Double
3      fun drive(): String
4      fun brake() {
5          println("Vehicle is slowing down")
6      }
7  }
8
9  // Super class of electric car
10 open class Car(override val maxSpeed: Double, val name: String, val
    brand: String): Drivable {
11      open var range: Double = 0.0
12
13      fun extendedRange(amount: Double) {
14          if (amount > 0) {
15              range += amount
16          }
17      }
18
19      open fun drive(distance: Double) {
20          println("Drove for $distance KMs")
21      }
22
23      override fun drive(): String {
24          return "Driving....."
25      }
26  }
27
28 // sub class of Car
29 class ElectricCar(
30     maxSpeed: Double,
31     name:String,
32     brand: String,
33     batteryLife: Double
34 ): Car(maxSpeed, name, brand) {
35     override var range = batteryLife * 6
```

```
36
37     override fun drive(distance: Double) {
38         println("Drove for $distance KMs on battery")
39     }
40
41     override fun drive(): String {
42         return "Drove for $range KMs on electricity"
43     }
44
45     override fun brake() {
46         super<>.brake()
47         println("Brake from electric car")
48     }
49 }
50
51 fun main() {
52     var audiA3 = Car(220.0, "A3", "Audi")
53     var teslaS = ElectricCar(240.0, "S-Model", "Tesla", 85.0)
54
55     audiA3.drive(200.0)
56     teslaS.drive(200.0)
57     teslaS.drive()
58
59     teslaS.brake()
60     audiA3.brake()
61 }
```

To override the non-abstract method `brake()` we need to specify interface name with method using **super** keyword as **super**<interface\_name>.methodName() for immediate parent. For sub class then we only use the **super**.methodName().
